

4.3.2 Complementation algorithm

Let $\mathcal{A} = (Q, q_0, \rightarrow, Q_f)$ an NFA.

Our goal is to construct an NFA $\bar{\mathcal{A}}$ with $L(\bar{\mathcal{A}}) = \overline{L(\mathcal{A})}$

Key idea:

Define an equivalence $\sim_{\mathcal{A}} \subseteq \Sigma^* \times \Sigma^*$ on words depending on how they move in \mathcal{A}

↳ coarse enough to have finitely many classes

↳ fine enough to capture what is/is not in $L(\mathcal{A})$ by classes.

Recall:

$q \xrightarrow{u} q'$ means there are states q_1, \dots, q_n so that

$$q \xrightarrow{a_0} q_1 \xrightarrow{a_1} \dots \xrightarrow{a_n} q' \text{ and } u = a_0 \dots a_n.$$

Define

$q \xrightarrow{u}_{\text{fin}} q'$ if $q \xrightarrow{u} q'$ so that at least one intermediary state is final.

Observation:

• $q \xrightarrow{u}_{\text{fin}} q'$ implies $q \xrightarrow{u} q'$ and

• $q \xrightarrow{u} q_j$ and $q_j \xrightarrow{v} q'$ with $q_j \in Q_f$ then $q \xrightarrow{uv}_{\text{fin}} q'$.

Definition (Transition equivalence):

Transition equivalence $\sim_{\mathcal{A}} \subseteq \Sigma^* \times \Sigma^*$ is defined by

$u \sim_{\mathcal{A}} v$ if for all $q, q' \in Q$ we have

$q \xrightarrow{u} q'$ iff $q \xrightarrow{v} q'$ and

$q \xrightarrow{u}_{\text{fin}} q'$ iff $q \xrightarrow{v}_{\text{fin}} q'$.

Intuitively:

Equivalence $u \sim_{\mathcal{A}} v$ means u and v yield the same state changes in \mathcal{A} (even when considering intermediary final states).

Ifs there are only finitely many states in A , equivalence \sim_A has finite index.

Lemma:

For every NFA $A = (Q, q_0, \rightarrow, Q_f)$, equivalence $\sim_A \subseteq \Sigma^* \times \Sigma^*$ has finitely many classes.

Proof:

First condition: $|Q|^2$ pairs of states

Second condition: $|Q|^2$ pairs of state

Choices of whether $q \xrightarrow{u} q'$ and $q \xrightarrow{u} \text{fin } q'$:
 $2^{|Q|^2}$ many equivalence classes.

13

Lemma: Consider an arbitrary NFA A .

Every equivalence class $[u]_{\sim_A} = \{v \in \Sigma^* \mid u \sim_A v\}$ is a regular language.

The technique used in the proof is important.

Proof:

Let $A = (Q, q_0, \rightarrow, Q_f)$.

For $q, q' \in Q$ define two languages

$$L_{q,q'} := \{u \in \Sigma^* \mid q \xrightarrow{u} q'\}$$

$$L_{q,q'}^{\text{fin}} := \{u \in \Sigma^* \mid q \xrightarrow{u} \text{fin } q'\}$$

Both languages are regular:

$$L_{q,q'} = L(A_{q,q'}) \text{ with } A_{q,q'} = (Q, q, \rightarrow, \{q'\})$$

// q as initial state, q' as final state

// $A_{q,q'}$ a finite automaton

$$L_{q,q'}^{fin} = L(\tilde{M}_{q,q'}^{fin}) \text{ with } \tilde{M}_{q,q'}^{fin} = (Q \times \{0,1\}, (q,0), \rightarrow', \{(q',1)\})$$

where $t = \begin{cases} 0 & \text{if } q \notin Q_F \\ 1 & \text{otherwise} \end{cases}$ and $(\hat{q}, i) \xrightarrow{a'} (\tilde{q}, j)$ if $\hat{q} \xrightarrow{a} \tilde{q}$

// set flag to 1
// when initial
state is final

$$j = \begin{cases} 0 & \text{if } i=0 \text{ and } q' \notin Q_F \\ 1 & \text{otherwise} \end{cases}$$

// q as initial state, q' as final state
// \tilde{M} a finite automaton
// set flag to 1 when final state found
// only accept with flag

We have

$$[L_u]_{\tilde{M}} = \bigcap_{q,q' \in Q} \widetilde{L}_{q,q'} \cap \widetilde{L}_{q,q'}^{fin}$$

where

$$\widetilde{L}_{q,q'} := \begin{cases} L_{q,q'} & \text{if } q \xrightarrow{u} q' \\ \overline{L_{q,q'}} & \text{otherwise} \end{cases}$$

$$\widetilde{L}_{q,q'}^{fin} := \begin{cases} L_{q,q'}^{fin} & \text{if } q \xrightarrow{u}_{fin} q' \\ \overline{L_{q,q'}^{fin}} & \text{otherwise} \end{cases}$$

- Its the set of states in \tilde{M} is finite, so is the intersection.
- We argued that $L_{q,q'}$ and $L_{q,q'}^{fin}$ are regular languages.
 - ↳ Regular languages are closed under complementation
 - ↳ and closed under finite intersections.

So $[L_u]_{\tilde{M}}$ is a regular language.

□

Although equivalence $\sim_{\mathcal{A}}$ has infinitely many classes
 it is fine enough so that its classes
 \hookrightarrow either fully belong to $L(\mathcal{A})$ or
 \hookrightarrow do not intersect $L(\mathcal{A})$.

Lemma:

Consider an NFA \mathcal{A} , two classes $[u]_{\sim_{\mathcal{A}}}$ and $[v]_{\sim_{\mathcal{A}}}$ of $\sim_{\mathcal{A}}$,
 and $w \in [u]_{\sim_{\mathcal{A}}} \cdot ([v]_{\sim_{\mathcal{A}}})^{\omega}$ an ω -word.

If $w \in L(\mathcal{A})$ then $[u]_{\sim_{\mathcal{A}}} \cdot ([v]_{\sim_{\mathcal{A}}})^{\omega} \subseteq L(\mathcal{A})$.

Proof:

Homework.

Corollary:

Let \mathcal{A} an NFA, $[u]_{\sim_{\mathcal{A}}}$ and $[v]_{\sim_{\mathcal{A}}}$ two classes of $\sim_{\mathcal{A}}$,
 and $w \in [u]_{\sim_{\mathcal{A}}} \cdot ([v]_{\sim_{\mathcal{A}}})^{\omega}$ an ω -word.

If $w \in \overline{L(\mathcal{A})}$ then $[u]_{\sim_{\mathcal{A}}} \cdot ([v]_{\sim_{\mathcal{A}}})^{\omega} \subseteq \overline{L(\mathcal{A})}$.

We now show that every word $\bar{w} \in \Sigma^{\omega}$ falls into such a
 composition of equivalence classes $[u]_{\sim_{\mathcal{A}}} \cdot ([v]_{\sim_{\mathcal{A}}})^{\omega}$.
 As a consequence, Σ^{ω} can be interpreted as

The proof is an application of Ramsey's Theorem.

Lemma:

Consider an NFA \mathcal{A} . For every word $w \in \Sigma^{\omega}$ there are
 classes $[u]_{\sim_{\mathcal{A}}}$ and $[v]_{\sim_{\mathcal{A}}}$ so that $w \in [u]_{\sim_{\mathcal{A}}} \cdot ([v]_{\sim_{\mathcal{A}}})^{\omega}$.

Proof:

Let $w = a_0 a_1 a_2 \dots \in \Sigma^\omega$.

Consider the following coloring of (V, E) with $V = \mathbb{N}$.

Let

$$f(\{i, j\}) := [a_i \dots a_{j-1}]_{\sim R} \quad \text{with } i < j.$$

Since $\sim R$ has only finitely many classes,

Ramsey's theorem applies and gives

- an equivalence class $[V]_{\sim R}$ and
 - an infinite subset $S \subseteq \mathbb{N}$
- so that

$$f(\{i, j\}) = [V]_{\sim R} \quad \text{for all } i < j \text{ in } S.$$

This means

$$[a_i \dots a_{j-1}]_{\sim R} = [V]_{\sim R}, \text{ so } a_i \dots a_{j-1} \sim_R V,$$

which means $a_i \dots a_{j-1} \in [V]_{\sim R}$.

Let $i_0 \in S$ minimal.

Then

$$w \in [a_{i_0} \dots a_{i_0-1}]_{\sim R} \cdot ([V]_{\sim R})^\omega.$$

Note that every word $a_0 \dots a_{i_0-1}$ belongs to its own equivalence class, $a_0 \dots a_{i_0-1} \in [a_0 \dots a_{i_0-1}]_{\sim R}$.

Theorem (Büchi '62)

Let A an NFA. Then $\overline{L(A)}$ is effectively ω -regular.

Proof:

$$\overline{L(A)} = \bigcup [u]_{\sim R} \cdot ([V]_{\sim R})^\omega$$
$$[u]_{\sim R} \cdot ([V]_{\sim R})^\omega \cap L(A) = \emptyset$$

Note that there are finitely many classes.

Thus this language is ω -regular.

Effectiveness:

- Determine all classes $\{L_i\}_{i \in \mathbb{N}}$ by automata constructions:
 - ↳ Pick the state changes $q \xrightarrow{a} q'$ that should / should not hold for the class.
 - ↳ Construct the corresponding automata $A_{q,q'}$ and $\bar{A}_{q,q'}$ (or their complements)
 - ↳ Intersect the languages as stated in Lemma above.
- ω -iteration of regular languages and concatenation of regular with ω -regular languages can be (effectively) performed on the corresponding automata. So $\{L_i\}_{i \in \mathbb{N}}, (\{L_i\}_{i \in \mathbb{N}})^\omega$ can be represented (effectively) by an NBR $A_{\{L_i\}_{i \in \mathbb{N}}, (\{L_i\}_{i \in \mathbb{N}})^\omega}$.
- Intersection of $L(A_{\{L_i\}_{i \in \mathbb{N}}, (\{L_i\}_{i \in \mathbb{N}})^\omega})$ with $L(A)$ can be computed by parallel composition.
- Emptiness of $L(A_{\{L_i\}_{i \in \mathbb{N}}, (\{L_i\}_{i \in \mathbb{N}})^\omega} \parallel A)$ decidable.
- Finite union of ω -regular languages is ω -regular.

By Theorem in homework, we can as well represent $\bigcup_{i \in \mathbb{N}} \{L_i\}_{i \in \mathbb{N}}, (\{L_i\}_{i \in \mathbb{N}})^\omega$ by an NBR.

Corollary:

Given an NBR A , we can effectively construct an NBR \bar{A} with $L(\bar{A}) = \overline{L(A)}$.

Later on, we give a direct construction.

5. Decision procedures

Goal of automata constructions

Use decision procedures for NBT languages to

- ↳ solve model checking $R \models \varphi$
- ↳ solve satisfiability of a formula φ
- ↳ solve validity of a formula φ

In this chapter, consider corresponding algorithmic problems:

- ↳ Emptiness: $L(A) = \emptyset$?
- ↳ Universality: $L(A) = \Sigma^*$?
- ↳ Inclusion: $L(A) \subseteq L(B)$?

Even if problems are mutually encodable,
dedicated decision procedures make sense: complementation expensive.

5.1 Universality with Ramsey

- Recent algorithm by Fogarty and Vardi '10.
- Related recent approach by Raskin, Doyen, De Wulff, Maquet

Fix an NBT $A = (Q, q_0, \rightarrow, Q_f)$.

As before,

$$u \sim_A v \quad \text{iff} \quad \begin{aligned} & q \xrightarrow{u} q' \quad \text{iff} \quad q \xrightarrow{v} q' \quad \text{and} \\ & q \xrightarrow{u} p q' \quad \text{iff} \quad q \xrightarrow{v} p q' \quad \text{for all } q, q' \in Q. \end{aligned}$$

characterise equivalence class $[u]_A$ by
two sets of pairs of states:

$$R_{[u]_A} := \{ (q, q') \in Q \times Q \mid q \xrightarrow{u} q' \}$$

$$R_{[u]_A}^{pin} := \{ (q, q') \in Q \times Q \mid q \xrightarrow{u} p q' \}$$

Technically, sets of pairs of states $R, S \subseteq Q \times Q$
are relations on Q .

Their composition is

$R; S := \{(q, q') \in Q \times Q \mid \exists q'' : (q, q'') \in R \text{ and } (q'', q') \in S\}$.
(also denoted by $S \circ R$)

With this point of view, we can construct equivalence classes in \sim_{π} by relational composition.

Lemma:

$$\bullet R_{[E]_{\sim \pi}} = \{(q, q) \mid q \in Q\}$$

$$R_{[E]_{\sim \pi}}^{tr} = \{(q, q) \mid q \in Q_F\}$$

$$\bullet R_{[a]_{\sim \pi}} = \{(q, q') \in Q \times Q \mid q \xrightarrow{a} q'\}$$

$$R_{[a]_{\sim \pi}}^{tr} = \{(q, q') \in Q \times Q \mid q \xrightarrow{a} q' \text{ and } q \in Q_F \text{ or } q' \in Q_F\}$$

$$\bullet R_{[uv]_{\sim \pi}} = R_{[u]_{\sim \pi}} ; R_{[v]_{\sim \pi}}$$

$$R_{[uv]_{\sim \pi}}^{tr} = (R_{[u]_{\sim \pi}}^{tr} ; R_{[v]_{\sim \pi}}) \cup (R_{[u]_{\sim \pi}} ; R_{[v]_{\sim \pi}}^{tr})$$
