

## 10.5 Robustness for Parameterized Programs

Motivation: Libraries cannot make assumptions on the number of threads executing their functions.

Goal: Solve robustness for parameterized programs.

Definition (Parameterized programs):

- Syntactically, a parameterized program  $P = \{t_1, \dots, t_k\}$  consists of a finite number of threads (like a normal parallel program).
- Semantically, a parameterized program represents a family of parallel programs, so-called instances:  
for every vector  $I = (n_1, \dots, n_k) \in \mathbb{N}^k$ ,  
instance  $P(I)$  has  $n_i$  copies of thread  $t_i$ .

The parameterized robustness problem is as follows:

Given: A parameterized program  $P$ .

Problem: Does  $\text{Tr}_{\text{TSO}}(P(I)) = \text{Tr}_{\text{seq}}(P(I))$  hold  
for all instances  $P(I)$  of  $P$ ?

Approach:

- With instrumentation,  
instance  $P(I)$  is not robust iff  
there is an attack  $\mathcal{A}$  so that  
 $P(I)_{\mathcal{A}}$  reaches a goal configuration.
- Impossible to instrument every instance  $P(I)$ , infinitely many.  
Instead, instrument  $P$  directly, turning  $P$  into  $P_{\mathcal{A}}$   
which is now a parameterized program.

### Caveful:

- ↳ Only one copy of  $t_{\mathcal{A}}$  should act as attacker.
- The remaining copies of  $t_{\mathcal{A}}$  have to behave like helpers.
- ↳ Hence,  $t_{\mathcal{A}}$  has to be instrumented both, as attacker and as helper.
- ↳ To make sure a single thread becomes the attacker, introduce a flag that is set atomically from 0 to 1 (by the thread acting as attacker).
- Atomic instructions like test-and-set can be added to our programming model without harm for the theory.

• Apart from this change

$P(I)_{\mathcal{A}}$  and  $P_{\mathcal{A}}(I)$  coincide.

### Theorem:

$\mathcal{A}$  parameterized program  $P$  is not robust

iff there is an attack  $\mathcal{A}$  so that

an instance  $P_{\mathcal{A}}(I)$  of the parameterized program  $P_{\mathcal{A}}$  reaches a goal configuration under  $\mathcal{S}$ .

### From parameterized programs over finite domains to Petri nets:

Consider parameterized programs over finite domains.

Goal: Show that <sup>(1)</sup>reachability of a goal configuration in an instance of  $P_{\mathcal{A}}$  can be formulated as a coverability problem for Petri nets.

Idea: Threads never use their identities, hence there is no need to track their identities. Instead, we count how many instances of each thread we in a certain (local) configuration.

The technique is known as counter abstraction

### Construction:

### Theorem:

Robustness for parameterized programs over finite domains is decidable in  $2\text{EXPSPACE}$  and  $\text{EXPSPACE}$ -hard, already in the Boolean case.

### Proof:

Coverability for Petri nets is  $\text{EXPSPACE}$ -complete.

↳ We reduce parameterized robustness to coverability in an exponentially large Petri net.

This gives a  $2\text{EXPSPACE}$  upper bound.

↳ For the lower bound, we reduce coverability to SC-reachability for parameterized programs (with atomic test-and-set).

Then hardness of robustness follows like in the non-parameterized case.  $\square$
